## 1 General case for $y = Ax$

$$\boxed{\text{original}} \quad y_j = \sum_i a_{ij} x_i. \quad (1)$$

Equivariance implies:

$$\begin{aligned} \boxed{\text{swapped}} \quad y_j(\sigma(x_j \ x_k)x) &= y_k \quad \boxed{\text{original}} \\ \sum_{i \neq j, k} a_{ij} x_i + a_{kj} x_j + a_{jj} x_k &= \sum_{i \neq j, k} a_{ik} x_i + a_{jk} x_j + a_{kk} x_k. \end{aligned} \quad (2)$$

Comparing coefficients yields:

$$\begin{aligned} a_{ij} &= a_{ik} & \forall j, k, (i \neq j, k) \\ a_{kj} &= a_{jk} & \forall j, k \\ a_{jj} &= a_{kk} & \forall j, k. \end{aligned} \quad (3)$$

In other words, the matrix  $A$  is of the form:

$$A = \alpha I + \beta 11^T. \quad (4)$$

## 2 Case for $y_k = A_k x \cdot x$

The general form of a “quadratic” vector function is:

$$y = (Ax) \cdot x + Bx + C. \quad (5)$$

We just focus on the quadratic term  $(Ax) \cdot x$ :

$$\boxed{\text{original}} \quad y_k = \sum_j \left[ \sum_i a_{ij}^k x_i \right] x_j. \quad (6)$$

Note that the matrix  $A$  is “3D” and has  $N \times N \times N$  entries.

Equivariance implies:

$$\boxed{\text{swapped}} \quad y_k(\sigma(x_k \ x_h)x) = y_h \quad \boxed{\text{original}} \quad (7)$$

$$\sum_{j \neq h, k} \sum_{i \neq h, k} a_{ij}^k x_i x_j + a_{hh}^k x_k^2 + a_{kh}^k x_h x_k + a_{hk}^k x_k x_h + a_{kk}^k x_h^2 = \sum_{j \neq h, k} \sum_{i \neq h, k} a_{ij}^h x_i x_j + a_{hh}^h x_h^2 + a_{kh}^h x_k x_h + a_{hk}^h x_h x_k + a_{kk}^h x_k^2$$

which yields:

$$\begin{aligned} a_{ij}^h &= a_{ij}^k & \forall h, k, (i \neq h, k, j \neq h, k) \\ a_{hh}^h &= a_{kk}^k & \forall h, k \\ a_{hh}^k &= a_{kk}^h & \forall h, k \\ a_{kh}^k + a_{hk}^k &= a_{kh}^h + a_{hk}^h & \forall h, k. \end{aligned} \quad (8)$$

How many different colors?

$$\begin{aligned} N = 3 & \dots 14 & / & 27 \\ N = 4 & \dots 26 & / & 64 \\ N = 5 & \dots 42 & / & 125 \\ N = 6 & \dots 92 & / & 216 \end{aligned} \quad (9)$$

There would be  $N$  **blocks** of  $N \times N$  matrices.

All diagonals consists of 2 colors, regardless of  $N$  (from 2nd and 3rd equations). This leaves  $N(N-1)$  non-diagonal entries per block.

Non-diagonal entries of different blocks are equal, if the block indices are different from the row and column indices. Out of  $N$  blocks there would be 2 different sets of non-diagonal weights. (This comes from the 1st equation.)

The last equation causes non-diagonal weights to have a certain symmetry about the diagonal.

### 3 With output space “folded in half”

Now suppose the output is only 1/2 the dimension of the input. Define a new form of equivariance such that the input permutation would act on the output as “folded in half”.

In other words, equivariance is changed to:

$$\boxed{\text{swapped}} \quad y_k \cdot \sigma(x_k \ x_h) = y_h \text{ or } y_{h-N/2} \quad \boxed{\text{original}} \quad (10)$$

where  $\tau$  is  $\sigma$  acting on  $y$  as double its length and identifying  $y_i = y_{i+N/2}$ .

#### 3.1 Linear case

Just notice that the dimension of  $y$  is halved:

$$\boxed{\text{original}} \quad y_j = \sum_i a_{ij} x_i. \quad (11)$$

“Folded” equivariance implies:

$$\boxed{\text{swapped}} \quad y_j(\sigma(x_j \ x_k)x) = y_k \quad \boxed{\text{original}} \quad (12)$$

$$\sum_{i \neq j, k} a_{ij}x_i + a_{kj}x_j + a_{jj}x_k = \sum_{i \neq j, k} a_{ik}x_i + a_{jk}x_j + a_{kk}x_k$$

with the restriction  $j \in \{1, \dots, N/2\}$ , and  $k \in \{1, \dots, N\}$ .

The constraints obtained are same as before, except that index ranges are different:

$$\begin{aligned} a_{ij} &= a_{ik} & \forall j, k, (i \neq j, k) \\ a_{kj} &= a_{jk} & \forall j, k \\ a_{jj} &= a_{kk} & \forall j, k \end{aligned}$$

These constraints give rise to a matrix of this form (for the  $6 \times 3$  case, numbers represent different colors):

$$\begin{array}{cccccc} 5 & 1 & 1 & 2 & 3 & 4 \\ 1 & 5 & 1 & 2 & 3 & 4 \\ 1 & 1 & 5 & 2 & 3 & 4 \end{array} . \quad (13)$$

This pattern is obtained from my Python code.

### 3.2 Quadratic case
